D. D. Brush
PATENT ATTORNEY

Sir:

Transmitted herewith in triplicate is the Appeal Brief in
this application with respect to the Notice of Appeal filed on April
12, 2004.

FEE FOR FILING APPEAL BRIEF

Pursuant to 37 C.F.R. 1.17(c) the fee for filing the
Appeal Brief is \$330.00.

The Director is authorized to charge any additional fees
associated with this paper or credit any overpayment to Deposit
Account No. 23-1123. A duplicate copy of this communication is
enclosed.

Respectfully submitted,

WESTMAN, CHAMPLIN & KELLY, P.A.

D. J. B.
PATENT ATTORNEY

Sir:

This is an appeal from an Office Action dated January 12, 2004 in which claims 23-25 were finally rejected.

REAL PARTY IN INTEREST

Seagate Technology LLC, a corporation organized under the laws of the state of Delaware, and having offices at 920 Disc Drive, Scotts Valley, CA 95066, has acquired the entire right, title and interest in and to the invention, the application, and any and all patents to be obtained therefor, as set forth in the Assignment filed with the patent application and recorded on Reel 010510, frame 0106.

RELATED APPEALS AND INTERFERENCES

There are no known related appeals or interferences, which will directly affect or be directly affected by or have a bearing on the Board's decision in this appeal.

STATUS OF THE CLAIMS

I. Total number of claims in the application.

Claims in the application are:

1-26

II. Status of all the claims.

06/21/2004 WABDELRI 00000053 09469597 330.00 DP

A.	Claims cancelled:	none
B.	Claims withdrawn but not cancelled:	none
C.	Claims pending:	1-26
D.	Claims allowed:	1-22
E.	Claims rejected:	23-25
G.	Claim allowable	26

III. Claims on appeal

The claims on appeal are: 23-25

STATUS OF AMENDMENTS

The claims have been previously presented and there are no unentered amendments after Final.

SUMMARY OF INVENTION

One embodiment in which the present invention is useful is shown in FIG. 1. FIG. 1 illustrates a data storage device 50 including an actuator assembly 56, which rotationally supports heads 60 for reading data from and/or writing data to discs 54. (only one head shown in FIG. 1). (Page 3, lines 12-18). Heads 60 are coupled to the actuator 56 via head suspension assemblies 72. One embodiment of the present invention is directed to a head vibration detector on the head suspension assembly for detecting vibration of the supported head or its air bearing. (Page 4, lines 3-6).

In the embodiment illustrated in FIG. 3, head vibration is detected by a transducer 102, which is supported on a head suspension assembly 72, and a detector 104 (Page 4, lines 7-9). Transducer 102 can operate in a detection mode or an actuation mode. (Page 6, lines 5-6). Transducer 102 can include a piezoelectric or electrostatic transducer, for example, for producing a transducer signal proportional to mechanical movement of the head suspension assembly 72 induced by head vibration while in the detection mode. (Page 6, lines 1-4). Opposed terminals 106, 108 of transducer 102 are orientated so that vibration or movement of transducer 102 along a detection axis 110 induces the

transducer signal. (Page 4, lines 9-13). Detector 104 receives the transducer signal and outputs a signal indicative of head vibration. (Page 4, lines 16-18). This signal can be monitored by a process controller 136, shown in FIG. 6, to assure that data is not lost or corrupted due to vibration. (Page 5, line 28 to page 6, line 1).

FIG. 7 illustrates an embodiment of process control circuitry for operating transducer 102 in the detection mode and the actuator mode. (Page 6, lines 10-12). For read/write operations, drive circuitry 130 provides a position signal to servo control processor 140 to operate voice coil motor 142 for head placement through actuator 56 (shown in FIG. 1). (Page 6, lines 12- 16). As shown by the dashed line, transducer 102 is coupled to the suspension assembly 72 of a respective head so that vibration of the head strains the transducer to produce a transducer signal. (Page 6, lines 16-19).

In the detection mode, detector 104 receives the transducer signal and outputs a level detected signal indicative of head vibration. (Page 6, lines 19-22). In the actuator mode, a microactuator controller 144 transmits a signal to transducer 102 to adjust dimensions of transducer providing for fine head placement capabilities. (Page 6, lines 22-25).

FIGS. 8-9 schematically illustrate an embodiment of a suspension based transducer 102, which is configured to laterally move the heads as illustrated by arrow 150 in the actuation mode and to detect head vibration in the detection mode. (Page 6, lines 26-30 and page 7, lines 24-27). As discussed above with reference to FIG. 3, opposed terminal plates (154 and 156 in FIG. 9) of transducer 102 are aligned so that mechanical movement of transducer 102 induces a potential across terminals of transducer 102 for detecting vibration modes of the head and its air bearing in the detection mode. (Page 7, lines 16-23). In the actuator mode, when a transducer signal is supplied to opposed terminals

154, 156, the length between ends 160, 162 expands and contracts depending upon the direction of the signal to laterally shift the position of the second suspension portion 72-2 relative to the first suspension portion 72-1 to actuate the heads as illustrated by arrow 150. (FIGS. 8 and 9, page 6, lines 9-15).

FIG. 10 illustrates an alternate embodiment of a suspension based transducer configured to microactuate a head as illustrated by arrow 150 in an actuation mode and aligned to induce a transducer signal for detecting head vibration in the detection mode. (Page 7, line 24 to page 8, line 5).

FIG. 11 is a flow chart, which illustrates operation of the transducer 102 in an actuation mode and a detection mode. (Page 8, lines 6-17).

ISSUES

- I. Whether claims 23-25 are supported by the specification under 35 U.S.C. §112, first paragraph.
- II. Whether claim 23 is novel in view of Evans.
- III. Whether claim 25 is novel in view of Evans.
- IV. Whether claim 24 is non-obvious over Evans in view of Novotny.

GROUPING OF CLAIMS

The following groupings of claims are made solely in the interest of consolidating issues and expediting this Appeal. No grouping of claims is intended to be nor should be interpreted as being any form of admission or a statement as to the scope or obviousness of any limitation.

- Group I. Claims 23;
- Group II Claim 24; and
- Group III. Claim 25

ARGUMENT

I. CLAIMS 23-25 ARE SUPPORTED BY APPLICANTS' SPECIFICATION AS REQUIRED BY 35 U.S.C. §112

Claims 23-25 were rejected under 35 U.S.C. §112, first paragraph as failing to comply with the written description requirement on the basis that claims 23-25 allegedly contain subject matter that was not described in the specification in such a way as to reasonably convey to one skilled in the relevant art that the inventor had possession of the claimed invention at the time the application was filed.

Claims 23-25 include, among other elements, "an actuator coupled to a movable suspension assembly; and a detector coupled to the actuator and configured to receive a signal proportional to vibration of the movable suspension assembly."

The Advisory Action dated March 31, 2004 suggests, ". . . in the specification as originally filed the transducer element (102) is not defined as an actuator per se. It is defined as a transducer having an actuation mode."

On its face, the reason stated in the Advisory Action for rejecting these claims under §112 is insufficient to support the rejection. If a transducer has "an actuation mode", it is an "actuator". If it were not an actuator, it could not actuate and would not have an actuation mode. This fact would be readily apparent to a person of ordinary skill in the art when looking at the present specification, within the meaning of §112, first paragraph.

The following sections illustrate the clear support provided by the specification for the elements appearing in claim 23.

A. The Specification Discloses an Actuator as Recited in Claim 23.

Claim 23 recites, "an actuator coupled to a movable

suspension assembly."

FIG. 7 illustrates a microactuator controller 144 coupled to a transducer 102. Transducer 102 is coupled to movable suspension assembly 72 (as shown by the dashed line).

As described on page 6, lines 5-10 with reference to FIG. 7, "[i]n one embodiment, the transducer operates between a detection mode and an actuator mode . . . in the actuator mode, the transducer receives a signal to move or actuate the head." (Emphasis added). Any person of ordinary skill in the art would understand this sentence to mean that the transducer is an "actuator".

This is further supported in FIG. 7 in that microactuator controller 144 controls the actuation of transducer 102. The specification states, "[i]n the actuation mode, a microactuator controller 144 transmits a signal to the transducer 102 to adjust the dimensions of the transducer 102 providing for fine head placement capabilities." If an element is controlled by a "microactuator controller" and that element "actuates" in an "actuator mode", as stated in the specification, it is an "actuator".

In the embodiment shown in FIGS. 8-9, actuation of the transducer "laterally shift[s] the position of the second suspension portion 72-2". (Page 7, lines 5-15).

Thus, transducer 102 is "an actuator coupled to a movable suspension assembly," as recited in claim 23.

Further support can be found in numerous other locations in the specification and drawings. (See e.g., FIGS. 8-10, page 6, lines 26-30 and page 7, lines 24-29).

The above interpretation is consistent with Webster's dictionary, where an "actuator" is defined as a device for moving or controlling something. Applicants' specification discloses a transducer element 102 coupled to the suspension assembly to actuate or move the head. (Applicants' specification).

**B. The Specification Discloses a Detector as Recited
in Claim 23.**

Claim 23 recites, "a detector coupled to the actuator and configured to receive a signal proportional to vibration of the movable suspension assembly."

FIG. 7 illustrates a detector 104 coupled to transducer 102 (an actuator as described above).

As described with reference to FIG. 7, ". . . transducer 102 is coupled to the suspension assembly of the heads so that vibration of the heads strains the transducer to produce a transducer signal. In the detection mode, detector 104 receives the transducer signal and outputs a level detected signal indicative of head vibration." (Emphasis added).

As described on page 6, lines 1-4, "[t]ransducer 102 can be a piezoelectric or electrostatic transducer for producing a transducer signal proportional to mechanical movement of the head suspension assembly 72 induced by head vibration."

Based on this explicit description, a person of ordinary skill in the art would understand that the detector 104 is coupled to an actuator (transducer 102) and configured to receive a signal proportional to vibration of the movable suspension assembly 72, as recited in claim 23.

Thus, the elements of claim 23 are fully supported by the written description and the rejection of claim 23 and its dependent claims 24-25 under §112, first paragraph should be reversed.

II. CLAIM 23 IS NOVEL IN VIEW OF EVANS ET AL.

Claim 23 was rejected under §102(e) as being anticipated by Evans et al., U.S. Patent No. 5,862,015.

As discussed above, claim 23 includes a movable suspension assembly, an actuator coupled to a movable suspension assembly, and a detector coupled to the actuator and configured to

receive a signal from the actuator proportional to vibration of the movable suspension assembly. "

A. Evans et al.

Evans et al. is directed to a head suspension having a resonance feedback transducer. As shown in FIG. 1, head suspension assembly 8 includes a strain transducer circuit 10, which functions as a strain gauge. (Col. 3, lines 27-29 and 55-56). Because transducer circuit 10 is mounted to head suspension assembly 8, strain in head suspension assembly 8 causes strain in transducer circuit lead 32, varying the electrical resistance of the transducer circuit. (Col. 4, lines 57-61).

FIG. 3 shows a block diagram of a system of monitoring off-neutral motion, which is described in column 5, lines 1-54. The change in resistance is converted to a voltage by converter 17, and servo control system 19 uses this information to control actuator system 21. The actuator system can include a primary and/or a secondary or micro-actuator.

B. Evans et al. do not Disclose the Elements of Claim 23.

Evans et al. do not disclose "a detector coupled to the actuator and configured to receive a signal from the actuator proportional to vibration of the movable suspension assembly," as recited in claim 23.

Looking at the block diagram in FIG. 3 of Evans et al. Evans et al. do not disclose that servo control system 19, converter circuit 17 or transducer circuit 10 receive a such a signal from an actuator. Evans et al. do not teach that actuator system 21 provides a signal that is proportional to vibration of a movable suspension assembly. Further, Evans et al. do not teach that transducer 10 is an actuator. It is a simple strain gauge that senses strain.

Since Evans et al. do not teach each and every element of claim 23, Applicants respectfully request that the rejection of

claim 23 under §102(e) be reversed.

III. CLAIM 25 IS NOVEL IN VIEW OF EVANS ET AL.

Claim 25 was rejected under §102(e) as being anticipated by Evans et al., U.S. Patent No. 5,862,015.

Claim 25 further includes "a controller coupled to the actuator and configured to transmit a signal to the actuator to move the movable suspension assembly."

The Final Action suggests element 19 (the servo control system in FIG. 3) "is a controller coupled to the actuator as claimed."

In contrast, Evans et al. do not disclose a controller coupled to the actuator as claimed. Servo control system 19 is coupled to actuator system 21. However, servo control system 19 is not coupled to an actuator that provides "a signal proportional to vibration of the movable suspension assembly," as required by claim 23 from which claim 25 depends. Thus, Evans et al. does not teach a controller coupled to an actuator as defined in the claim.

Since Evans et al. do not teach each and every element of claim 25, Applicants respectfully request that the rejection of claim 25 under §102(e) be reversed.

IV. CLAIM 24 IS NON-OBVIOUS OVER EVANS ET AL. IN VIEW OF NOVOTNY

Claim 24 was rejected under 35 U.S.C. § 103(a) as being unpatentable over Evans in view of Novotny U.S. Patent No. 6,362,542 on the basis that Novotny discloses a piezoelectric or electrostatic microactuator for precision head placement. (Col. 1, lines 34-37).

Claim 24 recites that the actuator is a piezoelectric or electrostatic actuator. However, claim 24 depends from claim 23. Thus, claim 24 requires such a piezoelectric or electrostatic actuator to provide a detector with "a signal from the actuator

proportional to vibration of the movable suspension assembly."

Novotny does not teach or suggest a piezoelectric or electrostatic actuator that provides a detector with a signal that is proportional to vibration of a movable suspension assembly. Therefore, even if Evans et al. and Novotny were combined as the Examiner suggests, the resulting combination would still fail to teach or suggest the invention recited in claim 24.

Applicants respectfully request that the rejection of claim 24 under §103(a) be reversed.

Respectfully submitted,

Appendix A

CLAIMS

1. (Allowed) A disc drive comprising:
 - a disc rotationally coupled to a chassis;
 - a movable head suspension assembly having a head coupled thereto movable relative to a surface of the disc;
 - a transducer supported on the movable head suspension assembly and configured to induce a transducer signal proportional to movement of the head;
 - a vibration detector configured to detect a transducer signal amplitude above a threshold amplitude and output a level detected signal indicative of head vibration.
2. (Allowed) The disc drive of claim 1 wherein the level detected signal is indicative of head-disc contact.
3. (Allowed) The disc drive of claim 1 wherein the vibration detector includes a frequency filter.
4. (Allowed) The disc drive of claim 3 wherein the frequency filter is configured to detect at least one of a bending mode or torsion mode.
5. (Allowed) The disc drive of claim 1 wherein the transducer is a piezoelectric material.
6. (Allowed) The disc drive of claim 1 wherein the transducer is an electrostatic transducer.

7. (Allowed) The disc drive of claim 1 and further comprising:
a process controller coupled to the detector and configured to receive the outputted level detected signal and output a process command to reexecute a write command in drive memory.
8. (Allowed) The disc drive of claim 1 and further comprising:
a controller coupled to the transducer on the movable head suspension assembly and configured to transmit a signal to the transducer to move the head.
9. (Allowed) The disc drive of claim 1 wherein the disc drive includes a plurality of discs rotationally coupled to the chassis and a plurality of movable head suspension assemblies having heads coupled thereto to read or write to surfaces of the plurality of discs and including a transducer coupled to each of the plurality of movable head suspension assemblies.
10. (Allowed) The disc drive of claim 19 wherein the transducer is configured to operate between a detection mode and an actuation mode, in the detection mode, the transducer detecting the vibration associated with the head suspension assembly and in the actuation mode the transducer receiving a signal to energize the transducer to move a head of the head suspension assembly.
11. (Allowed) The disc drive of claim 10 including:
a microactuator controller coupled to the transducer and configured to operate the transducer in the actuation mode.
12. (Allowed) A method for operating a disc drive comprising steps of:

- (a) providing a transducer supported on a movable head suspension assembly having a head coupled thereto configured to generate a transducer signal indicative of head vibration; and
- (b) detecting a signal amplitude of the transducer signal above a threshold amplitude and outputting a level detected signal indicative of the head vibration.

13. (Allowed) The method of claim 12 wherein the transducer is a piezoelectric transducer.

14. (Allowed) The method of claim 12 and further comprising the step of:

- (c) transmitting a signal to the transducer on the movable suspension assembly to move the head.

15. (Allowed) The method of claim 12 and further comprising the step of:

- (c) transmitting a command to rewrite a write command in drive memory in response to the level detected signal indicative of the head vibration.

16. (Allowed) The method of claim 12 and comprising the step of

- (c) filtering the transducer signal to detect vibration frequencies of the head.

17. (Allowed) The method of claim 12 wherein the disc drive includes a plurality of head suspension assemblies and further comprising:

- (c) individually detecting the head vibration for each of the plurality of head suspension assemblies.

18. (Allowed) The method of claim 12 including a microactuator controller coupled to the transducer and configured to transmit a signal to the transducer to move the head and comprising the step of:

- (c) selectively operating the disc drive in a detection mode and an actuation mode, in the detection mode the transducer detecting the head vibration and in the actuation mode, the transducer moving the head.

19. (Allowed) A drive assembly comprising:

- a movable head suspension assembly; and
- a detector coupled to a transducer on the movable head suspension assembly that provides a signal indicative of a vibration associated with the head suspension assembly and the detector outputs a level detected signal that is responsive to the vibration being greater than a threshold value.

20. (Allowed) The method of claim 12 and comprising the step of:

- (c) filtering the transducer signal to detect one of bending or torsion mode vibration frequencies.

21. (Allowed) The assembly of claim 19 in which the vibration is caused by head vibration.

22. (Allowed) The assembly of claim 19 wherein the detector includes a filter configured to pass a signal responsive to vibration frequencies associated with the head suspension assembly.

23. (On Appeal) An assembly comprising:

- a movable suspension assembly;

an actuator coupled to the movable suspension assembly;
and
a detector coupled to the actuator and configured to
receive a signal from the actuator proportional to
vibration of the movable suspension assembly.

24. (On Appeal) The assembly of claim 23 wherein the actuator is
one of a piezoelectric or electrostatic actuator.

25. (On Appeal) The assembly of claim 23 and further comprising:
a controller coupled to the actuator and configured to
transmit a signal to the actuator to move the
movable suspension assembly.

26. (Allowable) The assembly of claim 23 including a controller
configured to operate the actuator between an actuation mode to
position a head of the movable suspension assembly and a detection
mode to detect vibration of the head of the movable suspension
assembly.

[57] **ABSTRACT**

A head suspension assembly including a load beam having a rigid region, a mounting region on a proximal end of the load beam, and a flexure on a distal end of the load beam. The flexure has a read/write head attachment region for supporting a read/write head on the distal end of the load beam. Deformation of the head suspension assembly displaces the head attachment region. A strain transducer circuit that acts as a strain gauge is mounted on the head suspension assembly. The resistance of the transducer circuit varies with strain in the circuit, which, in turn, varies with displacement of the read/write head. The magnitude of resistance change of the transducer circuit indicates the magnitude of head off-neutral motion.

REFERENCE TO RELATED APPLICATION

This application claims the benefit of U.S. Provisional application Ser. No. 60/018,167, filed May 23, 1996 abandoned.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates generally to suspensions for supporting read/write heads over recording media. In particular, the present invention relates to a head suspension assembly with a strain transducer circuit thereon for detecting motion of the head suspension assembly out of a neutral position.

2. Description of the Related Art

Information storage devices typically include a read/write head for reading and/or writing data onto a storage medium such as a magnetic disk within a rigid disk drive. An actuator mechanism driven by a servo control is used to position the head at specific radial locations or tracks on the magnetic disk. Both linear and rotary type actuators are well known in the art. Between the actuator and the head, a head suspension is required to support the head in proper orientation relative to the disk surface.

The head suspension carries the read/write head so that the head can "fly" over the surface of the rigid disk while the disk is spinning. The head is typically located on a head slider having an aerodynamic design so that the head slider flies on an air bearing generated by the spinning disk. The combination of the head slider and the head suspension is referred to as a head suspension assembly. The head suspension includes a load beam which has a radius or spring section, a rigid region, and a flexure. The flexure is a spring or gimballing connection typically included between the head slider and the rigid section of the load beam so that the head slider can move in the pitch and roll directions of the head to accommodate fluctuations of the disk surface. The mounting region of the load beam is typically attached to an actuator arm which supports the suspension assembly over the rotating disk. A base of the actuator arm is coupled to an actuator.

When no external forces (with the exception of gravity) are acting on the head suspension assembly to deform it in any way, it is in a "neutral un-loaded" state. When the head is flying over the spinning surface of a disk, and is acted upon only by the force of the air bearing generated by the spinning disk, the head suspension assembly is in a "neutral loaded" state. However, the head suspension assembly can experience deformations that cause motion of the head away from either the neutral loaded or neutral un-loaded positions.

One way these deformations can occur involves a head suspension's tendency to bend and twist in a number of different modes, known as resonant frequencies, when driven back and forth at certain rates. Any such bending or twisting of a suspension can cause the position of the head to deviate from its neutral loaded or neutral un-loaded position.

Common bending and twisting modes of suspensions are generally known and discussed, for example, in the Yumura et al. U.S. Pat. No. 5,339,208 and the Hatch et al. U.S. Pat. No. 5,471,734. Modes which result in lateral or transverse motion (also known as off-track motion) of the head slider are particularly detrimental since this motion causes the

head slider to move from the desired track on the disk toward an adjacent track. The three primary modes which produce this transverse motion are known as the sway, first torsion, and second torsion modes. The sway mode is a lateral bending mode in which the suspension bends in a transverse direction along its entire length. The first and second torsion modes are twisting modes during which the suspension twists about a rotational axis which extends along the length of the suspension.

Deformations of the suspension can also be caused by a secondary-actuation or microactuation device designed to move the head relative to the remainder of the head suspension assembly. Such a microactuation device is disclosed in U.S. patent application Ser. No. 08/457,432 filed Jun. 6, 1995 by Jurgenson et al. for a Head Suspension with Tracking Microactuator now U.S. Pat. No. 5,657,188.

Whether generated by motion during resonant modes, a secondary actuation device, or other causes, it can be useful to monitor motion of the head away from a neutral loaded or neutral un-loaded position, that is, read/write head off-neutral motion. Information about head off-neutral motion caused by undesirable resonant vibrations can be used to actively damp such vibrations. Further, monitoring of the displacement of the head caused by a first actuator can be important to correct placement of the head by a second actuator.

SUMMARY OF THE INVENTION

The present invention provides a means for detecting the off-neutral motion of a head mounted on a head suspension assembly. This information can be used to correct head off-neutral motion, if necessary, so that read/write operations can be accomplished relatively quickly and accurately. It can also be used to determine the displacement of a magnetic head caused by a microactuation device to allow accurate placement of the head by a primary actuator. The head suspension assembly includes a load beam having a proximal end, a distal end, a mounting region on the proximal end, and a rigid region adjacent to the distal end. A flexure is at the distal end of the load beam. A strain transducer circuit is located on the head suspension assembly and detects strain in the head suspension assembly. In one embodiment, the flexure includes a head attachment region where the read/write head is attached. Deformation of the head suspension assembly displaces the head attachment region from a neutral position and subjects the head suspension assembly to strain. The strain transducer circuit detects the strain which allows detection of motion of the head attachment region out of the neutral position.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is an isometric view of a head suspension assembly including a strain transducer circuit on a load beam in accordance with the present invention.

FIG. 2a is an isometric view of the suspension assembly shown in FIG. 1 undergoing twisting motion in the first torsion mode.

FIG. 2b is an isometric view of the suspension assembly shown in FIG. 1 undergoing twisting motion in the second torsion mode.

FIG. 2c is an isometric view of the suspension assembly shown in FIG. 1 undergoing bending motion in the sway mode.

FIG. 3 is a block diagram showing a system for detecting motion of a head suspension assembly out of neutral position in accordance with the present invention.

FIG. 4 is a side view of laminated sheet material from which the head suspension shown in FIG. 1 can be fabricated.

FIG. 5 is a sectional view of the head suspension assembly shown in FIG. 1 taken along line 5—5.

FIG. 6 is a sectional view of the head suspension assembly shown in FIG. 1 taken along line 6—6.

FIG. 7 is an isometric view of a head suspension assembly including first and second strain transducer circuits in accordance with a second embodiment of the present invention.

FIG. 8 is an isometric view of a head suspension assembly including an actuator arm and first and second strain transducer circuits in accordance with a third embodiment of the present invention.

FIG. 9 is an isometric view of a head suspension assembly including an actuator arm and first, second, third, and fourth strain transducer circuits in accordance with a fourth embodiment of the present invention.

FIG. 10 is a top view of a head suspension assembly including a microactuation device and strain transducer circuit in accordance with a fifth embodiment of the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

A head suspension assembly 8 which includes a strain transducer circuit 10 in accordance with the present invention is illustrated generally in FIG. 1. As shown, head suspension assembly 8 includes a load beam 12 having a base or mounting region 14 on a proximal end, a flexure 16 on a distal end, a relatively rigid region 17 adjacent to the flexure, and a radius or spring region 18 between the base 14 and rigid region 17. The flexure 16 supports a head slider (not shown) which is mounted on a head attachment region 13 and which "flies" on an air bearing created by a spinning magnetic disk (not shown). The head slider supports a read/write head (not shown) for transferring data to, and reading data from the spinning magnetic disk. A base plate 20 is welded to base 14 for mounting the load beam 12 to a disk drive actuator arm (not shown). Flexure 16 is a spring connection provided between a head slider and the distal end of the load beam 12 which permits the head slider to move in pitch and roll directions so that it can compensate for fluctuations of the spinning disk surface above which the slider flies. Many different types of flexures, also known as gimbals, are known to provide the spring connection allowing for pitch and roll movement of the head slider and can be used with the present invention. First and second edge rails 23 and 24 are formed in transversely opposite sides of the rigid region 17 of load beam 12. Tab 26 which extends from base 14 is used to position and support read/write head lead wires (not shown), transducer circuit lead wires 28a and 28b, and electrical contacts 30.

The strain transducer circuit 10 is located in the transverse center of load beam 12 and functions as a strain gauge. Strain gauges are well known in the art and any suitable strain gauge is contemplated to be used with the present invention. In the embodiment of FIG. 1, individual transducer circuit lead 32 of transducer circuit 10 is formed from a single electrical lead which extends longitudinally back and forth in parallel sections connected at ends of the sections. Other orientations and configurations of circuit lead 32 are also within the ambit of the present invention. For example the electrical lead can be configured in a circular spiral or other non-parallel configurations. FIG. 5 is a sectional view of load beam 12 taken along line 5—5 and

showing transducer circuit lead 32. Lead wires 28a and 28b are connected to opposite ends of circuit lead 32 to form a continuous closed circuit between lead wires 28a and 28b. FIG. 6 is a sectional view of load beam 12 taken along line 6—6 and showing lead wires 28a and 28b. Lead wires 28a and 28b are connected to contacts 30 on tab 26.

Transducer circuit lead 32 is fabricated of a material in which the electrical resistance varies with strain on the material. In the embodiment of FIG. 1, circuit lead 32 is formed of Constantan, a commercially available nickel-copper alloy. Transducer circuit lead 32 can also be formed of any other material in which electrical resistance varies as the strain on the material varies.

When head suspension assembly 8 is acted upon by no external forces it is in a neutral un-loaded position. When the head suspension assembly 8 is acted on only by the force of the air bearing on which the slider flies, the head suspension assembly is in a neutral loaded (fly-height) position. Hereinafter, the term "neutral" will be used to refer to either the neutral un-loaded position or neutral loaded position. When the head suspension assembly 8 is in a neutral position, it holds the read/write head attachment region 13, and thereby the read/write head (not shown), in a neutral position with respect to a base 14 of the load beam 12. However, head suspension assembly 8 can elastically deform out of neutral position moving the head attachment region 13 out of neutral position. This causes read/write head off-neutral motion.

This kind of motion can occur as a result of motion in resonant modes causing oscillatory excursions of a head suspension assembly about its neutral position. As is discussed generally in the Description of the Related Art section of this document, when in operation, head suspension assemblies such as 8 bend and twist in a number of different modes, known as resonant frequencies, when driven back and forth at certain rates of speeds. FIG. 2a is an illustration of suspension assembly 8 undergoing twisting motion in what is known as the first torsion mode. FIG. 2b is an illustration of suspension assembly 8 undergoing twisting motion in what is known as the second torsion mode. In both the first and second torsion modes the load beam 12 of suspension assembly 8 twists or rotates about a central, longitudinally oriented rotational axis. FIG. 2c is an illustration of suspension assembly 8 undergoing bending motion in what is known as the sway mode. In the sway mode the load beam 12 bends about an axis that is perpendicular to the base of the load beam. Typically, the sway mode exhibits a slight twisting motion as well.

Read/write head off-neutral motion can also be caused by a microactuation device on a head suspension assembly, such as microactuator 338 shown in FIG. 10, intentionally designed to move a portion of the suspension assembly out of its neutral position.

Generally, the greater the motion of a head suspension assembly out of neutral position, the greater the strain thereon. Referring again to FIG. 1, because transducer circuit 10 is mounted to head suspension 8, strain in head suspension 8 causes strain in transducer circuit lead 32 of transducer circuit 10, varying the electrical resistance of transducer circuit 10. In this way, the electrical resistance of transducer circuit 10 varies with motion of the head attachment region 13 out of neutral position. This variation in resistance can be converted into an electrical signal using a wheatstone bridge or other methods known in the art, and used to monitor motion of the head attachment region out of neutral position, that is, read/write head off-neutral motion.

FIG. 3 shows a block diagram of a system to monitor read/write head off-neutral motion using the transducer circuit 10 in accordance with the present invention. A deformation of head suspension assembly 8 causes read/write head off-neutral motion. Deformation of head suspension assembly 8, as explained above, also causes strain in transducer circuit lead 32 which changes the electrical resistance of transducer circuit 10. The resistance of transducer circuit 10 can be detected across contacts 30 and can then be converted into a voltage by a resistance to voltage converter 17, such as a wheatstone bridge or other well known means. The converter 17 can then be electrically connected to a servo control system 19. In this way, the servo control system 19 can be provided with the head off-neutral motion information. If necessary, servo control system 19 can then act to correct or minimize head off-neutral motion through appropriate control of actuator system 21, which can include a primary and/or a secondary or micro-actuator which actuate head suspension 8. This would be desirable if, for example, head off-neutral motion was caused by resonance vibrations in head suspension assembly 8. Correction of head off-neutral motion may not be desirable, however, if it is intentionally caused by a micro-actuation device as shown in the embodiment shown in FIG. 10. In such a case, monitoring head off-neutral motion can still be important for correct placement of the load beam 12 by a primary actuator.

It should be noted that converter 17 can be incorporated onto the head suspension assembly itself by forming a wheatstone bridge on the suspension assembly from four strain transducer circuits as shown in FIG. 9.

The position at which transducer circuit 10 is located can be determined on the basis of the specific types of deformations that are desired to be monitored. As noted above, it is possible to use the transducer circuit 10 to detect whether the head suspension assembly 8 is undergoing motion in a resonant mode that could cause off-track error and increase read/write function time. Different resonant modes more severely strain different sections of the head suspension assembly. For monitoring off-neutral head motion in a resonant mode, it is desirable to locate the transducer circuit 10 at a location of relatively high strain for that particular resonant mode.

The location on a head suspension assembly that a particular mode strains most severely is dependent upon the design of the particular suspension assembly. Which section of a given suspension assembly is most strained for a given resonant mode (i.e. the location of the nodes for that mode) is generally known, can be determined empirically, or can be determined using methods of computer modeled finite element analysis known in the art. The transducer circuit can then be placed on the section of the suspension assembly that experiences relatively high strain during a condition of resonance in a chosen mode.

A method for manufacturing load beam 12 and transducer circuit 10 can be described with reference to FIGS. 4, 5 and 6. In the embodiment of FIG. 1, all the features of load beam 12 with the exception of the flexure 16 and baseplate 20 are manufactured from a single sheet of laminated material 40 shown in FIG. 4. FIG. 5 shows a sectional view of load beam 12 taken along line 5—5. FIG. 6 shows a sectional view of load beam 12 taken along line 6—6. Material 40 includes a lower layer 42 of stainless steel or other resilient material; an intermediate layer 44 of polyimide or other dielectric material overlaying the lower layer; and an upper layer 46 of Constantan or other material in which the resistance varies in relation to strain. Using etching or otherwise known

techniques, blanks having the desired external dimensions of load beam 12 are formed from the sheet of material 40. The lower layer 42 is patterned and etched to form base 14, spring region 18, rigid region 17, and first and second edge rails 23 and 24. Intermediate layer 44 and upper layer 46 are then patterned and etched to form transducer circuit lead 32, lead wires 28a and 28b, and contacts 30. First and second edge rails 23 and 24 are then formed in the edges of load beam 17. In other embodiments (not shown), transducer circuit 10 can be separately fabricated and bonded by adhesive or other means to a conventional or otherwise manufactured load beam. Also, additive processes, such as plating, sputtering, or vapor deposition, or other processes known in the art may be used to form the transducer circuit 10 on suspension 8.

FIG. 7 is an illustration of a suspension assembly including another embodiment of the present invention. Elements in FIG. 7 which are functionally similar to those of FIG. 1 are labeled with like numerals incremented by 100. As shown in FIG. 7, a head suspension assembly 108 includes a load beam 112 having a base or mounting region 114 on a proximal end, a flexure 116 on a distal end, a relatively rigid region 117 adjacent to the flexure, and a radius or spring region 118 between the base 114 and rigid region 117. Flexure 116 includes read/write head attachment region 113. An open region 111 is formed in the transverse center of spring region 118 forming a pair of spring arms 119a and 119b. In the embodiment of FIG. 7, strain transducer circuits 110a and 110b, which act as strain gauges, are mounted on spring arms 119a and 119b, respectively. Individual transducer circuit lead 132a of transducer circuit 110a is a single connected lead that extends longitudinally back and forth in parallel sections connected at ends of the sections. Lead wires 128a connect transducer circuit 110a to contacts 130a and lead wires 128b connect transducer circuit 110b to contacts 130b. Tab 126 supports contacts 130a and 130b. Head suspension assembly 108 can be manufactured in a manner similar to that of head suspension assembly 8 shown in FIG. 1.

In the embodiment shown in FIG. 7, the transducer circuits 110a and 110b are placed in a position of relatively high strain for either the first and second torsion modes or the sway mode.

FIG. 8 is an illustration of a head suspension assembly 208 including another embodiment of the present invention. In FIG. 8, the head suspension assembly 208 includes an actuator arm 207 to which the mounting region 14 of load beam 12 is attached. Actuator arm 207 is connected at base 206 to a servo actuator (not shown) and carries and positions load beam 12 above a spinning magnetic disk (not shown). A strain transducer circuit 234 which acts as a strain gauge is located on the actuator arm 207. In the embodiment of FIG. 8, individual transducer circuit lead 242 of transducer circuit 234 is a single connected lead which crosses longitudinally back and forth in parallel sections connected at the ends of the sections. As noted previously, other configurations of circuit lead 242 are also within the ambit of the present invention. Lead wires 236a and 236b connect to opposite ends of transducer circuit 234 to form a closed circuit between lead wires 236a and 236b. Tab 238 supports electrical contacts 240.

In the embodiment shown in FIG. 8, transducer circuit 10, as discussed above, detects deformation in load beam 12. Further, deformations of actuator arm 207 can cause motion of head attachment region 13 on flexure 16 out of a neutral position with respect to base 206 of actuator arm 207. Transducer circuit 242 detects deformation of actuator arm

207 and thereby detects read/write head off-neutral motion with respect to base 206 caused by deformation in actuator arm 207. The signals from transducer circuits 10 and 242 can be fed to a servo controller (not shown) to facilitate correction or control of head off-neutral motion as necessary.

Actuator arm 207 can be manufactured from a sheet of laminated material 40 as shown in FIG. 4 having a lower layer 42 of stainless steel or other resilient material, an intermediate layer 44 of polyimide or other dielectric, and an upper layer 46 of Constantan or other material in which electrical resistance varies with strain. Using etching or otherwise known techniques, blanks having the desired external dimensions of actuator arm 207 are formed from the sheet of material 40. The lower layer 42 is patterned and etched to form base 206 and tab 238. Intermediate layer 44 and upper layer 46 are then patterned and etched to form transducer circuit lead 242, lead wires 236a and 236b, and contacts 240. In other embodiments (not shown), transducer circuit 234 can be separately fabricated and bonded by adhesive or other means to a conventional or otherwise manufactured actuator arm. Load beam 12 can be mounted to actuator arm 207 by welding or other known means. Also, additive processes, such as plating, sputtering, or vapor deposition, or other processes known in the art may be used to form the transducer circuit 234 on actuator arm 207.

FIG. 9 is an illustration of a suspension assembly showing another embodiment of the present invention. Elements in FIG. 9 which are functionally similar to those of FIG. 1 are shown with like numerals incremented by 400. As shown in FIG. 9, a head suspension assembly 408 includes a load beam 412 having a base or mounting region 414 on a proximal end, a flexure 416 on a distal end, a relatively rigid region 417 adjacent to the flexure, and a radius or spring region 418 between the base 414 and rigid region 417. Flexure 416 includes read/write head attachment region 413. An open region 411 is formed in the transverse center of spring region 418 forming a pair of spring arms 419a and 419b. In the embodiment of FIG. 9, first and second strain transducer circuits 410a and 410c are mounted on spring arm 419a and third and fourth strain transducer circuits 410b and 410d are mounted on spring arm 419b. Transducer circuits 410a, 410b, 410c and 410d are electrically connected together by electrical lead 421 to form a wheatstone bridge circuit. This wheatstone bridge circuit is then connected by electrical leads 428a, 428b, 428c, and 428d to electrical contacts 430a, 430b, 430c, and 430d, respectively. In this way, read/write head off neutral motion of suspension assembly 408 can be detected directly as a voltage and the need for an external resistance to voltage converter is obviated. Head suspension assembly 408 can be manufactured in a manner similar to that of head suspension assembly 8 shown in FIG. 1.

FIG. 10 is an illustration of a suspension assembly showing yet another embodiment of the present invention. Elements in FIG. 10 which are functionally similar to those of FIG. 1 are shown with like numerals incremented by 300. FIG. 10 shows a head suspension assembly 308 including a load beam 312 having a base or mounting region 314 on a proximal end, a T-type flexure 316 on a distal end, a relatively rigid region 317 adjacent to the flexure, and a spring region 318 between the base 314 and the rigid region 317.

Flexure 316 includes a mounting portion 327, a pair of spaced arms 329a and 329b which extend from the mounting portion 327, and a cross member 331 which extends between the distal ends of arms 329a and 329b. The arms 329a and 329b and cross member 331 form gap 333 through

the distal end of flexure 316. A tongue 334 extends from the cross member 331 into gap 333 toward load beam base 314. Cross member 331 is offset from arms 329a and 329b so the plane of the cross member 331 and tongue 334 are offset from the plane of the arms 329a and 329b. Tongue 334 also includes a conventional load point dimple 335. A slider (not shown) with a read/write head (not shown) is adhesively bonded or otherwise mounted to tongue 334 to form a head suspension assembly from suspension 308.

A microactuator 338 is positioned at the distal end of tongue 334 and is configured to move tongue 334 laterally between arms 329a and 329b in response to tracking control signals. The details of such a microactuator is disclosed in U.S. patent application Ser. No. 08/457,432 filed Jun. 6, 1995 by Jurgenson et al. for a Head Suspension with Tracking Microactuator. Any other suitable microactuator is also contemplated to be used in conjunction with the present invention. As microactuator 338 moves tongue 334, the read/write head (not shown) is moved beneath load point dimple 335 to be placed above a correct information track in a spinning magnetic disk (not shown).

As tongue 334 is moved between arms 329a and 329b the distal end of tongue 334 elastically deforms and causes strain in tongue 334. A strain transducer circuit 310 which acts as a strain gauge is located at the distal end of tongue 334. Individual transducer circuit lead 332 is configured to extend longitudinally back and forth in parallel sections connected at ends of the sections. As above, other configurations of circuit lead 332 are also within the ambit of the present invention. Lead wires 328a and 328b connect to opposite ends of transducer circuit 310 to form a continuous closed circuit between lead wires 328a and 328b. Lead wires 328a and 328b connect to contacts 330 on tab 326.

Deformation of the distal end of tongue 334 causes strain therein. This strain causes strain in circuit lead 332 and increasing the resistance of transducer circuit 310. The resistance of transducer circuit 310 can be detected across contacts 330 and may be converted into a voltage by a resistance to voltage transducer (not shown) such as a wheatstone bridge or other known means. This signal can then be provided to a servo controller (not shown) and even fed back to microactuator 338 to monitor the position of the read/write head over information tracks (not shown). Head suspension assembly 308 can be manufactured in a manner similar to that of head suspension assembly 8 shown in FIG. 1.

Though the present invention has been described with reference to preferred embodiments, those skilled in the art will recognize that changes can be made in form and detail without departing from the spirit and scope of the invention.

What is claimed is:

1. A head suspension assembly in which resonance mode motion can induce strain, the head suspension assembly comprising:

a load beam having a proximal end, a distal end, a mounting region on the proximal end, a rigid region adjacent to the distal end and a spring region between the rigid region and the mounting region;

a flexure for supporting a read/write head at the distal end of the load beam; and

at least one strain transducer circuit on the head suspension assembly for detecting strain therein such that the strain transducer circuit detects resonance mode motion of the head suspension assembly.

2. The head suspension assembly of claim 1 wherein the strain transducer circuit is located on the load beam.

3. The head suspension assembly of claim 1 wherein the load beam includes a spring region between the rigid region and the mounting region and further wherein the strain transducer circuit is located in the spring region.

4. The head suspension assembly of claim 1 wherein the strain transducer circuit is located on the rigid region of the load beam.

5. The head suspension assembly of claim 1 wherein the flexure includes a head attachment region for supporting a read/write head at the distal end of the load beam and wherein an elastic deformation of the head suspension assembly can displace the head attachment region from a neutral position and generate strain in the head suspension assembly.

6. The head suspension assembly of claim 5 wherein the strain transducer circuit has an electrical resistance which varies with strain in the head suspension assembly at a position of the strain transducer circuit thereon such that the resistance in the strain transducer circuit varies with deformation of the head suspension assembly to allow detection of motion of the head mounting region out of the neutral position.

7. The head suspension assembly of claim 6 wherein the strain transducer circuit is located on the load beam.

8. The head suspension assembly of claim 6 wherein the strain transducer circuit includes a single strain gauge lead having an electrical resistance that varies with strain on the lead.

9. The head suspension assembly of claim 8 wherein the strain gauge lead is formed of Constantan.

10. The head suspension assembly of claim 5 wherein the strain transducer circuit is located in the spring region.

11. The head suspension assembly of claim 10 including a first strain transducer circuit and a second strain transducer circuit wherein the spring region has an open region that divides the spring region into first and second radius arms and the first strain transducer circuit is located on the first radius arm and the second strain transducer circuit is located on the second radius arm.

12. The head suspension assembly of claim 1 wherein the strain transducer circuit is on the flexure.

13. The head suspension assembly of claim 1 including first, second, third and fourth strain transducer circuits wherein the spring region has an open region that divides the spring region into first and second radius arms and the first and second strain transducer circuits are located on the first radius arm, the third and fourth strain transducer circuits are located on the second radius arm, and the first, second, third and fourth strain transducer circuits are interconnected to form a wheatstone bridge circuit.

14. A head suspension assembly comprising:

a load beam having a proximal end, a distal end, a mounting region on the proximal end, a rigid region adjacent to the distal end and a spring region between the rigid region and the mounting region;

a flexure having a head attachment region for supporting a read/write head and at the distal end of the load beam, the head attachment region displaceable from a neutral position, such displacement causing strain in the head suspension assembly;

a microactuator on the head suspension assembly between the mounting region and the head attachment region and to displace the head attachment region from the neutral position and along a transverse tracking axis; and

at least one strain transducer circuit on the head suspension assembly for detecting strain in the head suspension assembly wherein displacement of the head attachment region from the neutral position caused by the microactuator is detected by the strain transducer circuit.

15. The head suspension assembly of claim 14 wherein the strain transducer is located on the load beam.

16. The head suspension assembly of claim 14 wherein the strain transducer circuit has an electrical resistance which varies with strain in the head suspension assembly at a position of the strain transducer circuit thereon.

17. The head suspension assembly of claim 16 wherein the strain transducer circuit includes a single strain gauge lead having an electrical resistance that varies with strain on the lead.

18. A head suspension assembly in which resonance mode motion can induce strain, comprising:

a load beam having a proximal end, a distal end, a mounting region on the proximal end, a rigid region adjacent to the distal end and a spring region between the rigid region and the mounting region;

an actuator arm having a proximal end and a distal end, the proximal end of the load beam mounted to the distal end of the actuator arm;

a flexure for supporting a read/write head and at the distal end of the load beam; and

at least one strain transducer circuit on the head suspension assembly for detecting strain in the head suspension assembly such that the strain transducer circuit detects resonance frequency vibrations of the head suspension assembly.

19. The head suspension assembly of claim 18 wherein the strain transducer circuit has an electrical resistance which varies with strain in the head suspension assembly at a position of the strain transducer circuit thereon.

20. The head suspension assembly of claim 18 wherein the strain transducer circuit is located on the actuator arm.

21. The head suspension assembly of claim 18 including a first strain transducer circuit and a second strain transducer circuit wherein the first strain transducer circuit is located on the actuator arm and the second strain transducer circuit is located on the load beam.

(57) **ABSTRACT**

A slider assembly for selectively altering a position of a transducing head with respect to a track of a rotatable disc having a plurality of concentric tracks includes a slider body having a main portion and a head portion separated by a gap. The head portion carries the transducing head. The slider body is arranged to be supported by a support structure over a surface of the rotatable disc. A pair of structural elements are disposed on opposite side surfaces of the slider body between the main portion and the head portion across the gap. At least one of the structural elements is a microactuator responsive to electrical control signals to selectively bend to alter the position of the head portion with respect to the main portion of the slider body. The structural elements may be complementary microactuators. The microactuators may be formed by a process involving forming the microactuators on a slider substrate or on a row of sliders, forming the microactuators on a slider stack, or separately forming the microactuators and attaching the microactuators to a slider stack.

PIEZOELECTRIC MICROACTUATOR FOR PRECISE HEAD POSITIONING

CROSS-REFERENCE TO RELATED APPLICATION(S)

This application claims priority from Provisional Application No. 60/055,874 filed Aug. 15, 1997 for "Piezoelectric Head Moving Microactuator For Ultrahigh Track Density Magnetic Recording Drives" by V. Novotny.

BACKGROUND OF THE INVENTION

The present invention relates to a disc drive microactuator, and more particularly to a high resolution head positioning mechanism having one or more piezoelectric elements attached to a slider as a bendable cantilever for selectively moving a head portion of the slider radially with respect to circumferential data tracks of a rotatable disc.

The track density, or radial spacing, between concentric data tracks on magnetic discs continues to increase, requiring greater precision in head positioning. Conventionally, head positioning is accomplished by operating an actuator arm with a large-scale actuator motor, such as a voice coil motor, to position a head on a flexure at the end of the actuator arm. The large-scale motor lacks sufficient resolution and bandwidth to effectively accommodate high track-density discs. Thus, a high resolution head positioning mechanism is necessary to accommodate the more densely spaced tracks.

One promising design for high resolution head positioning involves employing a high resolution microactuator in addition to the conventional low resolution actuator motor, thereby effecting head positioning through dual-stage actuation. Various microactuator designs have been considered to accomplish high resolution head positioning, including piezoelectric, electromagnetic, electrostatic, capacitive, fluidic, and thermal actuators. Various locations for the microactuator have been suggested, including on the slider, on the gimbal, at the interface between the gimbal and the slider, and on the actuator arm, for example. However, the previous designs all had shortcomings that limited the effectiveness of the microactuator, such as substantial performance limitations or manufacturing complexities, which made the microactuator designs impractical. An effective microactuator design must provide high acceleration in positioning the head while also generating sufficiently large and accurate displacements to precisely move the head across several data tracks on the disc.

There is a need in the art for a microactuator design to provide high resolution head positioning with superior bandwidth performance characteristics that can be implemented by simple and readily available manufacturing processes.

BRIEF SUMMARY OF THE INVENTION

The present invention is a slider assembly for selectively altering a position of a transducing head with respect to a track of a rotatable disc having a plurality of concentric tracks. The slider assembly includes a slider body having a main portion and a head portion separated by a gap. The head portion carries the transducing head. The slider body is arranged to be supported by a support structure over a surface of the rotatable disc. A pair of structural elements are disposed on opposite side surfaces of the slider body between the main portion and the head portion across the gap. At least one of the structural elements is a microactuator responsive to electrical control signals to selectively bend to

2

alter the position of the head portion with respect to the main portion of the slider body. The structural elements are preferably complementary microactuators.

Another aspect of the present invention is a process of forming a pair of microactuators on each of a plurality of sliders. A slider substrate is formed comprising main portions of the sliders, and a sacrificial layer is deposited on the slider substrate. Head portions each carrying a transducing head are then formed on the sacrificial layer. A row of sliders is separated from the slider substrate, an air-bearing surface is formed on each of the sliders in the row, and notches are cut between individual sliders in the row. Microactuators are formed between the main portions and the head portions of the sliders on side surfaces of the sliders in the notches. Alternatively, the microactuator processing may be performed at the wafer level, prior to the steps of separating the slider substrate into rows and defining the air-bearing surfaces of the sliders in the rows. Individual sliders are separated from the slider row such that a pair of microactuators are on opposite side surfaces of each of the sliders. The sacrificial layer is removed to form a gap between the main portions and the head portions of the sliders.

A further aspect of the present invention is a process of forming a microactuator on each of a plurality of sliders. A slider substrate is formed comprising main portions of the sliders, and a sacrificial layer is deposited on the slider substrate. Head portions each carrying a transducing head are then formed on the sacrificial layer. A row of sliders is separated from the slider substrate, and an air-bearing surface is shaped for each of the sliders in the row. Individual sliders are separated from the row of sliders, and a plurality of the individual sliders are glued together to form a slider stack. A plurality of microactuators are formed on side surfaces of each of the sliders in the slider stack, and the sacrificial layer is etched away to form a gap between the main portions and head portions of each of the sliders. The sliders are separated from each other by dissolving the glue. Alternatively, the plurality of microactuators may be separately formed and attached to the side surfaces of the sliders stack, and then separated into individual microactuators for each of the sliders in the slider stack.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a top view of a disc drive actuation system for positioning a slider over tracks of a disc.

FIG. 2 is a top view of a slider including piezoelectric microactuators for high resolution head positioning according to the present invention.

FIG. 3 is a side view of the slider shown in FIG. 2.

FIG. 4 is an enlarged top view of a portion of the slider shown in FIG. 2 illustrating the construction of the piezoelectric microactuator according to a first embodiment of the present invention.

FIG. 5 is an enlarged top view of a portion of the slider shown in FIG. 2 illustrating the construction of the piezoelectric microactuator according to a second embodiment of the present invention.

FIG. 6 is a diagram illustrating a unimorph piezoelectric bending motor in its neutral position.

FIG. 7 is a diagram illustrating the unimorph piezoelectric bending motor of FIG. 6 in its actuated position.

FIG. 8 is a diagram illustrating a bimorph piezoelectric bending motor configured for parallel operation.

FIG. 9 is a diagram illustrating a bimorph piezoelectric bending motor configured for series operation.

3

FIG. 10 is a diagram of a typical slider substrate wafer.

FIG. 11 is a perspective view of a portion of the substrate wafer shown in FIG. 10 in enlarged detail, illustrating a process according to a third embodiment of the present invention.

FIG. 12 is a top view of a slider row processed according to a fourth embodiment of the present invention.

FIG. 13 is a side view of the slider row shown in FIG. 12, with a portion shown in enlarged detail to illustrate the microactuator.

FIG. 14 is a perspective view of a stack of sliders on which to form piezoelectric microactuators according to a fifth embodiment of the present invention.

FIG. 15 is a perspective view of the stack of sliders shown in FIG. 10 with piezoelectric microactuators formed thereon according to the fifth embodiment of the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

FIG. 1 is a top view of a disc drive actuation system 10 for positioning slider 24 over a track 34 of disc 30. Actuation system 10 includes voice coil motor (VCM) 12 arranged to rotate actuator arm 16 around axis 14. Head suspension 18 is connected to actuator arm 16 at head mounting block 20. Flexure 22 is connected to an end of head suspension 18, and carries slider 24. Slider 24 carries a transducing head (not shown in FIG. 1) for reading and/or writing data on concentric tracks 34 of disc 30. Disc 30 rotates around axis 32, so that windage is encountered by slider 24 to keep it aloft a small distance above the surface of disc 30.

VCM 12 is selectively operated to move actuator arm 16 around axis 14, thereby moving slider 24 between tracks 34 of disc 30. However, for disc drive systems with high track density, VCM 12 lacks sufficient resolution and frequency response to position a transducing head on slider 24 over a selected track 34 of disc 30. Therefore, a higher resolution actuation device is necessary.

FIG. 2 is a top view and FIG. 3 is a side view of slider 24 including piezoelectric microactuator 42a and structural element 42b to enable high resolution positioning of head 41 according to the present invention. Slider 24 includes a head portion 40 carrying transducing head 41 and also includes air gap or space 44 between head portion 40 of slider 24 and the remaining portion of slider 24. Microactuator 42a and structural element 42b are disposed on the side surfaces of slider 24 near its distal end, connecting head portion 40 to the remainder of slider 24. Microactuator 42a is a structural element operable as a bendable cantilever to alter the position of head portion 40 with respect to main portion 38. Structural element 42b is preferably a microactuator similar and complementary to microactuator 42a, but may alternatively be a layer of structural material such as silicon nitride (Si_3N_4) or polysilicon, for example, to provide some flexibility while prevent undesired vibrations that could affect the position of transducing head 41. Transducing head 41 comprises an inductive write head and/or a magnetoresistive read head, for example, as is well known in the art. Transducing head 41 is desirably positioned directly over a data track on a rotating disc to read and/or write data from and/or to the disc.

In operation, slider 24 is coarsely positioned adjacent a selected data track by activating VCM 12 to move actuator arm 16 (FIG. 1) carrying slider 24. To finely position transducing head 41 over the selected track, control signals are applied to piezoelectric microactuator 42a to cause

4

bending of microactuator 42a and consequent bending of structural element 42b. When structural element 42b is a microactuator, control signals are also applied to microactuator 42b to cause bending complementary to microactuator 42a. Bending of microactuators 42a and 42b is controlled to selectively alter the position of transducing head 41 in the direction of arrows 46, thereby precisely positioning transducing head 41 directly over the selected track on the disc.

FIG. 4 is an enlarged top view of the distal portion of slider 24 illustrating the construction of piezoelectric microactuator 42a according to a first embodiment of the invention. Bottom electrode 50 connects head portion 40 to the remainder of slider 24 across gap 44. Piezoelectric element 52 is formed on bottom electrode 50, and top electrode 54 is formed on piezoelectric element 52. This configuration forms a cantilevered unimorph piezoelectric bending motor, the operation of which is described in detail below with respect to FIGS. 6 and 7.

FIG. 5 is an enlarged top view of the distal portion of slider 24 illustrating the construction of piezoelectric microactuator 42a according to a second embodiment of the invention. Structural layer 60 connects head portion 40 to the remainder of slider 24 across gap 44. Buffer layer 62 is formed on structural layer 60, and adhesive layer 64 is disposed on buffer layer 62. Bottom electrode 66 is formed on adhesive layer 64, and first piezoelectric element 68 is formed on bottom electrode 66. Shared electrode 70 is formed on piezoelectric element 68. A second piezoelectric element 72 is formed on shared electrode 70, and top electrode 74 is formed on piezoelectric element 72. An optional encapsulation layer 76 is formed over top electrode 74. This configuration of piezoelectric microactuator 42a forms a bimorph piezoelectric bending motor, the operation of which is discussed in detail later with respect to FIGS. 8 and 9.

In an exemplary embodiment, structural layer 60 is composed of silicon nitride (Si_3N_4) or polysilicon. Buffer layer 62 is preferably composed of silicon dioxide (SiO_2) or titanium dioxide (TiO_2). Adhesive layer 64 is preferably composed of titanium (Ti) or tantalum (Ta). Bottom electrode 66, shared electrode 70 and top electrode 74 are preferably formed of platinum (Pt). Piezoelectric elements 68 and 72 may be composed of zinc oxide (ZnO), lead zirconium titanate (PbZrTiO_3 , known as PZT), aluminum nitride (AlN) or polyvinylidene fluoride (PVDF). The zinc oxide material requires no annealing or low temperature annealing, while the PZT material requires high temperature annealing. Piezoelectric elements 68 and 72 may be deposited by sputtering, sol gel techniques or laser deposition, as is known in the art.

FIG. 6 is a diagram of a cantilevered unimorph bending motor 80 in its neutral position, and FIG. 7 is a diagram of cantilevered unimorph bending motor 80 in its actuated position. Unimorph bending motor 80 may be implemented by piezoelectric microactuator 42a described above with respect to FIG. 4. Unimorph bending motor 80 includes bottom electrode 82, piezoelectric element 84 and top electrode 86, and is restrained at one end by connection to a solid object such as slider 24. Terminal 88 connects bottom electrode 82 to a first potential and terminal 90 connects top electrode 86 to a second potential. Piezoelectric element 84 is poled in the direction indicated by arrow 91.

In operation, when the potential difference between terminals 88 and 90 (and consequently between bottom electrode 82 and top electrode 86) is applied across piezoelectric element 84, the element contracts along its length, forcing

5

bending of piezoelectric element 84 and electrodes 82 and 86 as indicated in FIG. 7. In this way, a deflection at the distal tip of bending motor 80 may be achieved. Conversely, application of an opposite potential difference between terminals 88 and 90 across piezoelectric element 84 results in opposite bending and opposite deflection at the distal tip of bending motor 80.

FIG. 8 is a diagram illustrating a cantilevered bimorph piezoelectric bending motor 100 configured for parallel operation. Bimorph piezoelectric bending motor 100 may be implemented by piezoelectric microactuator 42a described above with respect to FIG. 5. Bimorph piezoelectric bending motor 100 is restrained at one end by connection to a solid object such as slider 24. Bimorph piezoelectric bending motor 100 includes bottom electrode 102, first piezoelectric element 104, shared electrode 106, second piezoelectric element 108, and top electrode 110. In the "parallel" configuration depicted in FIG. 8, piezoelectric elements 104 and 108 are poled in the direction of arrows 118 and 120. A first voltage is applied at terminal 112 to bottom electrode 102, and at terminal 116 to top electrode 110. A second voltage is applied at terminal 114 to shared electrode 106. Thus, in the "parallel" configuration, piezoelectric element 108 will contract, and piezoelectric element 104 will expand, in response to the first and second voltages applied at the terminals. The result is a bending motion (shown in dashed lines) of bimorph piezoelectric bending motor 100, since one end of the motor is restrained by connection to slider 24. The amount of bending of the motor, and thus the amount of displacement of transducing head 41 on head portion 40 (FIG. 2) is precisely controlled by the voltages applied to terminals 112, 114 and 116. Applying opposite voltages to terminals 112, 114 and 116 causes similar bending in the opposite direction. Thus, bimorph piezoelectric bending motor 100 is able to provide high resolution positioning of head 41 over a selected track of a disc.

FIG. 9 is a diagram illustrating a cantilevered bimorph piezoelectric bending motor 100 configured for series operation. Bimorph piezoelectric bending motor 100 may be implemented by piezoelectric microactuator 42a described above with respect to FIG. 5. Just as in FIG. 8, bimorph piezoelectric bending motor 100 includes bottom electrode 102, first piezoelectric element 104, shared electrode 106, second piezoelectric element 108, and top electrode 110. Piezoelectric element 108 is poled in the direction of arrow 128 and piezoelectric element 104 is poled in the opposite direction, shown by arrow 130. A first voltage is applied at terminal 116 to piezoelectric element 108, and a second voltage is applied at terminal 112 to piezoelectric element 104. As a result, bimorph piezoelectric bending motor 100 bends as indicated in dashed lines, since one end of the motor is restrained by the connection to slider 24. Applying opposite voltages to terminals 112 and 116 causes similar bending in the opposite direction. The "series" configuration is the simplest and most economical, since it requires only two connections to the outside surfaces of piezoelectric elements 104 and 108. However, the "series" configuration yields less deflection per volt of applied potential than the "parallel" configuration shown in FIG. 8. The "parallel" configuration is more complex, requiring three electrical connections, the additional connection being made to shared electrode 106. Either of the configurations shown in FIGS. 8 and 9 are acceptable for effecting high resolution positioning of transducing head 41 (FIG. 2) over a selected track of a disc.

FIG. 10 is a diagram of a typical slider substrate wafer 150. Substrate wafer 150 is shown to comprise a plurality of

6

portions 152 used to form a plurality of sliders 24, and has a thickness equal to a desired length of the sliders.

FIG. 11 is a perspective view of a portion 152 of substrate wafer 150. The portion 152 shows a 3x3 array of sliders 24. Transducing heads 41 are formed on the top (trailing edge) surface of each slider 24 of wafer 150, as is known in the art. The portion 152 further has layers formed thereon according to the present invention. In order to form sliders 24 with a gap between main portions 38 and head portions 40, the substrate wafer is used to define only main portions 38 of sliders 24. Sacrificial layer 160 is deposited on the substrate wafer to define the region that will become the gap.

According to a third embodiment of the present invention, notches 172 are cut between columns of sliders 24 before wafer 150 is cut (along dotted lines 168) into slider rows. After notches 172 have been cut, multilayer piezoelectric microactuators are formed in notches 172. The details of the process of forming the microactuators essentially identical to the process discussed below with respect to FIG. 13, with long strips of materials being formed for several sliders rather than forming individual microactuators for each slider. Wafer 150 is then ready to be diced into slider rows along dotted lines 168, at which point the air-bearing surfaces of sliders 24 are formed.

FIG. 12 is a top view, and FIG. 13 is a side view with a portion shown in enlarged detail, of a slider row 170 processed according to a fourth embodiment of the present invention, with structural elements 42b being implemented as microactuators. Slider row 170 includes a plurality of sliders 24 each having an air-bearing surface 171 and notches 172 cut between sliders 24. Notches 172 are shown as trapezoidal in shape, which facilitates sidewall deposition of microactuator layers between sliders; alternatively, notches 172 may be right-angle cuts if more sophisticated sidewall deposition techniques are employed. Notches 172 are cut by a diamond saw, for example, and preferably do not extend through the entire height of sliders 24, so that sliders 24 remain attached to one another in slider row 170.

Microactuators 42a and 42b are formed in notches 172 on opposite sides of sliders 24. Photolithography is performed to define the regions where the electrodes and piezoelectric materials of microactuators 42a and 42b are to be deposited, with photoresist layers 177 being deposited to protect transducing head 41. Bottom electrode 50 is then deposited in notch 172, also extending onto the top surface of sliders 24. Piezoelectric element 52 is deposited and annealed on bottom electrode 50. If high annealing temperatures are required that are incompatible with the materials in transducing heads 41 of sliders 24, annealing may be performed by a localized laser heating process, for example. Preferably, piezoelectric element 52 is composed of a material that does not require annealing temperatures that are incompatible with heads 41. Top electrode 54 is then deposited on piezoelectric element 52, and poling of piezoelectric element 52 is performed at an elevated temperature. Bottom electrode 50 preferably extends on the top surface of sliders 24 beyond piezoelectric element 52 and top electrode 54 at regions 176, to provide easy access to bottom electrode 50 for electrical connection thereto. After bottom electrode 50, piezoelectric element 52 and top electrode 54 have been deposited, photoresist layers 177 used in the photolithography process to define the microactuator regions and protect transducing head 41 are removed and sliders 24 are separated from slider row 170 by dicing at lines 174. Sacrificial layer 160 between main portions 38 and head portions 40 of sliders 24 is also etched away to form the gap between those portions. Electrical connections are made to the microac-

tuator in a manner known in the art, such as through the flex circuit used to contact transducing head 41, and may be made on the top of the slider or on any other exposed surfaces of bottom electrode 50 and top electrode 54. Although microactuators 42a and 42b are only shown in FIG. 13 with bottom electrode 50, piezoelectric element 52 and top electrode 54 (as described above with respect to FIG. 4), it should be understood that microactuators 42a and 42b may be formed to include the layers described above with respect to FIG. 5.

FIGS. 14 and 15 are perspective views of a stack of sliders 24, illustrating a process of forming microactuator 42a and structural element 42b on sliders 24 according to a fifth embodiment of the present invention. Sliders 24 are each formed as described above with respect to FIGS. 11 and 12 by initially forming main portions 38 of sliders 24, depositing sacrificial layer 160 on the distal surface of main portions 38, and forming head portions 40 on sacrificial layer 160, with head portions 40 carrying transducing heads 41. Sacrificial layer 160 occupies the area that will become gap regions 44 between main portions 38 of sliders 24 and head portions 40. Sliders 24 are diced apart and then stacked and glued together lightly. Piezoelectric microactuator 42a and structural element 42b (which is preferably another microactuator) are either formed directly on slider row assemblies, with the microactuator areas defined by photolithography, for example, on side surfaces of the slider stack, or are separately formed in strips or sheets and then attached to the side surfaces of the slider stack, yielding the structure shown in FIG. 15. Microactuator 42a may be formed on a structural layer (such as layer 60 in FIG. 5) deposited on the side surfaces of the slider stack, or may be formed or attached directly on the side surfaces of the stack. Structural element 42b may be a microactuator similar and complementary to microactuator 42a, or may be a structural layer composed of silicon nitride (Si_3N_4) or polysilicon, for example. Where the layers of microactuators 42a and 42b are formed as sheets or strips along the side surfaces of the slider stack, the material layers are cut at regions 180 so that microactuators 42a and 42b do not extend all the way to the air-bearing surfaces of sliders 24. In the case where microactuator 42a and structural element 42b are formed on a separate substrate (which is subsequently removed) and attached to the slider stack, the multilayer sheets are ultimately separated into individual microactuators on each of the sliders 24 by a laser, for example. This separate formation and transfer process avoids potential temperature incompatibilities, since the potentially high temperature annealing of the piezoelectric material is not performed proximate to transducing head 41. Sacrificial layer 160 is then etched away to form gaps 44 between the main portions of sliders 24 and head portions 40 of the sliders. The glue holding sliders 24 together is then dissolved, leaving each individual slider with piezoelectric microactuator 42a and structural element 42b on its side surfaces across gap 44. Alternatively, the process described above could be performed on each slider individually, thereby increasing the number of steps involved to attach the microactuators to the sliders but eliminating the steps of initially gluing the sliders together, separating the microactuators and ultimately dissolving the glue to separate the sliders.

The present invention provides precise, high performance head positioning, with high acceleration in moving the head and sufficiently large and accurate head displacement to cover several data tracks. Only head portion 40 of slider 24 is moved by microactuator 42a (and structural element 42b, when it is implemented as a microactuator), minimizing the

total mass that is displaced and thereby enabling high acceleration of head 41. Additionally, moving only head portion 40 of slider 24 allows the microactuator to cancel resonance effects associated with the actuator arm and flexure, eliminating any track misregistration effects due to vibrations or the like resulting from those resonances. The microactuators are also readily manufacturable by simple existing fabrication techniques with only the addition of a sacrificial layer on the slider, minimizing the incremental cost of the microactuator-equipped disc drive.

Although the present invention has been described with reference to preferred embodiments, workers skilled in the art will recognize that changes may be made in form and detail without departing from the spirit and scope of the invention.

What is claimed is:

1. A disc drive slider and transducing head assembly for selectively altering a position of the transducing head with respect to a track of a rotatable disc having a plurality of concentric tracks, comprising:

a slider body having a discrete main portion and a discrete head portion separated by a gap, the head portion carrying the transducing head, the slider body being arranged to be supported by a support structure over a surface of the rotatable disc; and

means for connecting the head portion to the main portion of the slider body and for selectively altering the position of the head portion with respect to the main portion of the slider body.

2. A disc drive slider and transducing head assembly for selectively altering a position of the transducing head with respect to a track of a rotatable disc having a plurality of concentric tracks, comprising:

a slider body having a discrete main portion and a discrete head portion separated by a gap, the head portion carrying the transducing head, the slider body being arranged to be supported by a support structure over a surface of the rotatable disc; and

a pair of structural elements on opposite side surfaces of the slider body between the main portion and the head portion across the gap, at least one of the structural elements being a microactuator responsive to electrical control signals to selectively bend to alter the position of the head portion with respect to the main portion of the slider body.

3. The slider assembly of claim 2, wherein the microactuator comprises:

a bottom electrode;

a piezoelectric element on the bottom electrode; and

a top electrode on the piezoelectric element.

4. The slider assembly of claim 2, wherein the microactuator comprises:

a bottom electrode;

a first piezoelectric element on the bottom electrode;

a shared electrode on the first piezoelectric element;

a second piezoelectric element on the shared electrode; and

a top electrode on the second piezoelectric element.

5. The slider assembly of claim 4, wherein the microactuator further comprises:

a structural layer on one of the side surfaces of the slider body; and

an adhesive layer on the structural layer, the structural layer and the adhesive layer supporting the bottom electrode.

9

6. The slider assembly of claim 5, wherein the microactuator further comprises:

a buffer layer between the structural layer and the adhesive layer.

7. The slider assembly of claim 4, wherein the microactuator further comprises:

an encapsulation layer over the top electrode.

8. The slider assembly of claim 2, wherein each of the pair of structural elements is a microactuator responsive to electrical control signals to selectively complementarily bend to alter the position of the head portion with respect to the main portion of the slider body.

9. The slider assembly of claim 8, wherein each of the microactuators comprises:

a bottom electrode;

a piezoelectric element on the bottom electrode; and

a top electrode on the piezoelectric element.

10. The slider assembly of claim 8, wherein each of the microactuators comprises:

a bottom electrode;

a first piezoelectric element on the bottom electrode;

10

a shared electrode on the first piezoelectric element;

a second piezoelectric element on the shared electrode; and

a top electrode on the second piezoelectric element.

11. The slider assembly of claim 10, wherein each of the microactuators further comprises:

a structural layer on one of the side surfaces of the slider body; and

an adhesive layer on the structural layer, the structural layer and the adhesive layer supporting the bottom electrode.

12. The slider assembly of claim 11, wherein each of the microactuators further comprises:

a buffer layer between the structural layer and the adhesive layer.

13. The slider assembly of claim 10, wherein each of the microactuators further comprises:

an encapsulation layer over the top electrode.
